Framework study

Context

- Networks
- Distributed Systems (specially Dynamical networks like peer-to-peer or ad-hoc networks)

Constraints

- Management of dynamicity
- Fault tolerance
- Decentralized solutions

Motivation

Conception of solutions to classical problems of distributed algorithmic for dynamic networks

Distributed system

Model of distributed system

- Set of computing resources that communicates through channels
- $(G = (V, E))$

Communication model :

Messages passing model

Distributed algorithms

Definition

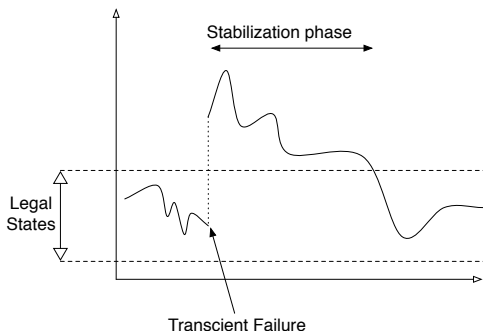

- Set of local algorithms
- Communication primitives (send, receive, ...)
- Local execution on each node

Fault Tolerance

Two approaches

- Robustness
 - Lots of impossibility results
 - Requires less restrictive assumptions
- **Self-stabilization**

Self-stabilization [Dijk74]

Two properties for self-stabilizing algorithms

- **Convergence** : starting from an illegal state and without failures, the algorithm converges to a legal state
- **Closure** : from a legal state and without failures occurrences, the algorithm remains in legal states

Plan

- 1 Introduction
 - Main context
 - Tools
- 2 Random walks characteristics evaluation
- 3 Fault tolerant Token Circulation
 - Loss of token
 - Corruption of token
 - Duplication of token
 - Application to ad-hoc networks
- 4 Network decomposition
 - Motivations
 - Informal description
 - Main mechanisms
- 5 Future works

Random walks

- Random moves in a graph
- Algorithmic procedure :

Reception of the token on the site i

Choose j uniformly at random among $Neigh(i)$

Send token to site j

Properties and mains characteristics

Percussion

On a finite graph, a random walk hits a node **in a finite time**. The mean time starting at a node i to hit node j is $h(i, j)$.

Coverage

On a finite graph, a random walk hits all nodes **in a finite time**. The mean time to visit all nodes is C .

Meeting

On a finite and non-bipartite graph, two random walks meet on the same node **in a finite time**. The mean time before two random walks meet is $Me(x_1, x_2)$.

Adaptativity

Adaptativity

Adaptativity

Circulating word

Definition

A circulating word is a message that collects information through its moves in the network.

[Lava86]

Circulating word + random walk

= Tools to collect and broadcast information.

Spanning tree construction

$M = \{5\}$

Spanning tree construction

$$M = \{2,5\}$$

Spanning tree construction

$$M = \{4,2,5\}$$

Spanning tree construction

$$M = \{5,4,2,5\}$$

Spanning tree construction

$$M = \{6,5,4,2,5\}$$

Spanning tree construction

$$M = \{1,6,5,4,2,5\}$$

Spanning tree construction

$$M = \{5, 1, 6, 5, 4, 2, 5\}$$

Spanning tree construction

$$M = \{2,5,1,6,5,4,2,5\}$$

Spanning tree construction

$$M = \{3,2,5,1,6,5,4,2,5\}$$

Adaptativity of the spanning tree

Circulating word moves permanently in the network
 \implies topological information are always updated

\implies Spanning tree is adaptive

At time T

$$M_T = \{5, 3, 2, 5, 4, 5, 1\}$$

At time $T + \Delta$

$$M_{T+\Delta} = \{5, 2, 1, 5, 3, 4, 5, 3, 2, 5, 4, 5, 1\}$$

Reduction of circulating word size

$$M = \{3, 2, 5, 1, 6, 5, 4, 2, 5\}$$

Circulating word size fixed at n

Plan

- 1 Introduction
 - Main context
 - Tools
- 2 Random walks characteristics evaluation
- 3 Fault tolerant Token Circulation
 - Loss of token
 - Corruption of token
 - Duplication of token
 - Application to ad-hoc networks
- 4 Network decomposition
 - Motivations
 - Informal description
 - Main mechanisms
- 5 Futur works

Computation of RW characteristics

Two approaches

- Markov chains
- **Analogy with electrical networks [DoSn84]**

Results from [CRST+97, Tet91]

- $h(i, j) = m \times R(i, j) + \frac{1}{2} \sum_{k \in V} \deg(k) \times (R(j, k) - R(i, k))$
- $m \times R \leq C \leq O(m \times R \times \log n)$

Computation of RW characteristics \implies Computation of $R(i, j)$

Electricity laws

Ohm's law

$$U_{AB} = R(A, B) \times i_{AB}$$

Kirchhoff's law

The sum of ingoing currents equals the sum of outgoing currents.

Millman's theorem

$$\frac{\frac{V-V_1}{r_1} + \frac{V-V_2}{r_2} + \dots + \frac{V-V_n}{r_n}}{\frac{1}{r_1} + \frac{1}{r_2} + \dots + \frac{1}{r_n}} = 0$$

Computation of $R(1, 2)$ 

$$\begin{cases} V_1 & & & & & = 1 \\ & V_2 & & & & = 0 \\ -V_1 & -V_2 & +3V_3 & -V_4 & -V_5 & = 0 \\ & & -V_3 & +3V_4 & -V_5 & = 0 \\ & -V_2 & -V_3 & -V_4 & +3V_5 & = 0 \end{cases} \implies \begin{cases} V_1 = 1 \\ V_2 = 0 \\ V_3 = \frac{1}{4} \\ V_4 = \frac{1}{2} \\ V_5 = \frac{1}{4} \end{cases}$$

$$\implies \begin{cases} i_2 = V_1 - V_2 = 1 \\ i_3 = V_1 - V_4 = \frac{1}{2} \\ i_1 = i_2 + i_3 = \frac{3}{2} \end{cases} \implies R(1, 2) = \frac{1}{\frac{3}{2}} = \frac{2}{3}$$

Computation of meeting time

Case of 2 RW

Token circulation

Primitive for :

- Election
- Efficient broadcast information
- Ressources allocation
- Structures Maintenance
- ...

Existing solutions

Based on the construction and maintenance of a virtual spanning structure
[ChWe02]

Communication failures

Self-stabilization in messages passing model

- loss of token

- Corruption of token

- Duplication of token

Plan

 - Main mechanisms
- 5 Futur works

Loss of token

Communication deadlock

Solution : Timeout

- At the reception of the token, a node reset its timeout
- If the timeout trigger, its node produce a new token

Timeout

Timeout

Timeout

Timeout

Timeout

Timeout

Timeout

Random walk policy as token's moves

[DoSW02] : $T = C \times i$

\implies Token creation still possible

There is no bound on the visiting time for a given node.

Reloading Wave

Our approach : a solution decided by the token

Broadcast a reset timeout order to all nodes

Principle

- A nodes receiving this wave, reset its timeout and continue the propagation.
- The wave is propagated periodically through an adaptive spanning tree stored in a circulating word inside the token

When propagate the wave ?

Remarks :

- After a visit, a node produces a new token in T time units
- The propagation of the wave takes in the worst case n time units

The token should propagate the reloading wave each $T - n$ time units

Example

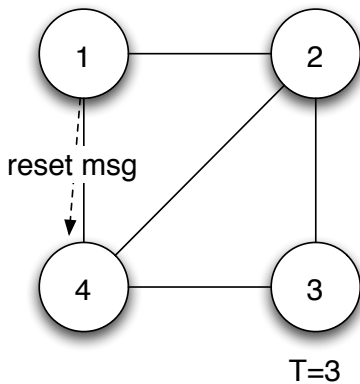

Example

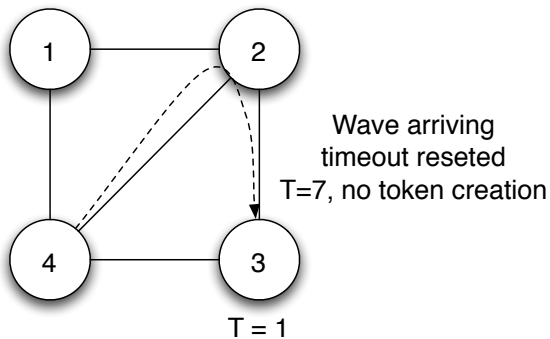

$T - n = \text{hop of the token}$
 \Rightarrow Reloading wave

Example

Example

Corruption of token

Solution

Test realized locally on each visited nodes.

$$M = \{5, 1, 6, 5, \mathbf{3}, 2, 5\}$$

Here $3 \notin \text{Neigh}(5)$, node 5 corrects the word : $M = \{5, 1, 6, 5\}$.

Duplication of token

A solution [IsJa90] (state model)

Meeting property

Mergure of topological information

Scheme of proof

Legal state \mathcal{EL}

- One complete and consistent token $JUCC$
- All nodes have been visited TSV

Lemmas

- A visited node can not produce new tokens
- The number of visited nodes increases
- All nodes become visited nodes : $\mathcal{C} \longrightarrow TSV$
- All tokens become consistent
- There exist at least one complete token
- For all configurations satisfying $\mathcal{C} \in TSV, \mathcal{C} \longrightarrow JUCC$

Theorem

$$\forall \mathcal{C}, \mathcal{C} \longrightarrow \mathcal{EL}$$

Plan

- 3 Fault tolerant Token Circulation
 - Loss of token
 - Corruption of token
 - Duplication of token
 - Application to ad-hoc networks
- 4 Network decomposition
 - Motivations
 - Informal description
 - Main mechanisms
- 5 Futur works

Model

Communication model

- Nodes communicate through radio waves of different range
- Oriented graph

Mobility

- Dynamic graph
- Nodes moves are a natural behavior
- Alternative solutions to flooding

Adaptation of circulating word management

Permanent algorithm \implies size grows infinitely

Our reduction technique

- based on usefull information.
- Allows to renew topological information used.

Adaptation of circulating word management

Remarks

The word $M = \langle 5, 4, 1, 3, 1, 2, 3, 4, 2, 5, 1 \rangle$ allows the construction of spanning tree enrooted on an arbitrary node

$$\underbrace{5, 4, 1, 3, 1, 2, 3, 4, 2, 5, 1}_{\text{Constructor Cycle}}$$

\implies our algorithm maintains a constructor cycle

Definition

A cycle $\mathcal{C}(i, j)$ in the word M is called *constructor* if :

$$\forall k \in \text{identities}(M), \exists l \in \{i, \dots, j\} \mid M[l] = k$$

Results

Our algorithm

- maintains an adaptive image of the network
- manages connexions and disconnexions
- bounds the size of the circulating word

Lemma

The size of the circulating word is bounded by $\frac{n^2+8n}{4}$

Simulations results

| | | | |
|--------------------------|-----|-----|------|
| Size of the network | 10 | 100 | 500 |
| Average size of the word | 17 | 225 | 1342 |
| Deviation | 1,9 | 20 | 192 |

k exclusion for ad-hoc network

k exclusion

- Extension of mutual exclusion
- At most k nodes can get critical section at a given time

k distinct tokens will circulate (Set of colors \mathcal{K})

Convergence

- Preliminary phase : deletion of corrupted tokens
- Production phase : produce at least one token by colors of \mathcal{K}
- Mergure phase : deletion of duplicated tokens

Mobility assumption

Self-stabilizing if :

An edge chosen to belong to the spanning tree should permit the propagation of the reloading wave during the time it belongs to this tree.

Plan

 - Loss of token
 - Corruption of token
 - Duplication of token
 - Application to ad-hoc networks
- 4 Network decomposition
 - Motivations
 - Informal description
 - Main mechanisms
- 5 Futur works

Motivation

Limitation of Random Walks

- In the most general case, Bounds on hitting, cover and meeting time are in $O(n^3)$
- Acceptable in theory but not for practical application.

Differents kinds of solutions (depending of the task to achieve)

- Increasing the number of random walks
- Build and maintain a hierarchical structure over the network

Plan

Annexion

Condition

The local random walk annexes a new node and

$$Nb_nodes \leq m_{max}$$

Operations

- Mark the new node with the LRW color.
- Update LRW information

Division

Condition

The local random walk annexes a new node and

$$Nb_nodes > m_{max}$$

Operations

- Update LRW information
- Send a wave on the spanning structure to split it into two parts

Submission

Condition

The local random walk visits another partition and

$$Nb_nodes < m_{min}$$

Operations

- Kill the LRW
- Propagate a wave through the partition to change the color partition

Plan

- 1 Introduction
 - Main context
 - Tools
- 2 Random walks characteristics evaluation
- 3 Fault tolerant Token Circulation
 - Loss of token
 - Corruption of token
 - Duplication of token
 - Application to ad-hoc networks
- 4 Network decomposition
 - Motivations
 - Informal description
 - Main mechanisms
- 5 Futur works

Futur works

Adaptive hierarchization

- Formal proof of the algorithm
- Self-stabilizing behaviour ?

Experimentations

- Topology of the partitions created
- Stability of the partition regarding the mobility of the network

Applications

Hybridation of random walks and *local flooding* for ad-hoc networks

RANDOM WALKS, A PARADIGM TO DESIGN DISTRIBUTED ALGORITHMS FOR DYNAMIC NETWORKS
